Types of Thrust Faults. • Fault bend folds - fault forms before the fold; deformation restricted to the hanging wall • Fault propagation folds - fault forms along with the folding; deformation in both the hanging wall and foot wall. Example of a fault-bend fold thrust fault at the WVU Geology Field Camp.

### **Structural Geology: Deformation of Rocks**

Structural Geology of Folded Rocks applies contemporary geometrical and textural techniques to the study of folded rocks and the structures associated with them. The Planar and linear structures of rocks are completely described. More than 480 photographs and the drawings illustrate observed relationships.

Structural Geology: Folds Definition Ø FOLDS may be defined as undulations or bends or curvatures developed in the rocks of the crust as a result of stresses to which these rocks have been subjected from time to time in the past history of the Earth.

Parts of a Fold: In a series of folds it is evident like waves. They consist of alternate crests and troughs. The crest of the fold is termed as anticline while the trough is called synclines. An anticline and syncline constitute a fold. Limbs or Flanks: Limbs or a flank of the fold is sloping side from the crest to the trough. Axial plane:

### **Structural geology of folded rocks (Book, 1966) [WorldCat.org]**

Folding is a manner for sedimentary and metamorphic rocks. Different layers in those rocks help geologist to understand structures. Last but not least, Anticlines (type of folding) are important types of "structural traps" in petroleum geology.

Chevron fold. Chevron folds are a structural feature characterized by repeated well behaved folded beds with straight limbs and sharp hinges. Well developed, these folds develop repeated set of v-shaped beds. They develop in response to regional or local compressive stress. Inter-limb angles are generally 60 degrees or less.

Use and importance. Structural geology is a critical part of engineering geology, which is concerned with the physical and mechanical properties of natural rocks. Structural fabrics and defects such as faults, folds, foliations and joints are internal weaknesses of rocks which may affect the stability of human engineered structures such as dams,...

Fold Dimensions. In a sedimentary stack where folds keep the same shape across the layers they are called harmonic folds. A fold is a kind of strain in the rock, and knowledge of the attitude and dimensions of folds helps us understand the direction and degree of stresses that have deformed the rock.

Fold (geology) Folds in Paleoproterozoic marble in Nunavut, Canada (with hammer for scale). Folds in alternating layers of limestone and chert in Crete, Greece. A geological fold occurs when one or a stack of originally flat and planar surfaces, such as sedimentary strata, are bent or curved as a

result of permanent deformation.

Folds in rocks vary in size from microscopic crinkles to mountainsize folds.They occur singly as isolated - folds and in extensive fold trains at all scales. A set of folds distributed on a regional scale constitutes a fold belt.

When solid, hard rock is bent (or folded) it invariably fractures and breaks because it is brittle (Figure 1).<sup>1</sup> Rock will bend only if it is still soft and pliable—"plastic" like modeling clay or children's Playdough. If such modeling clay is allowed to dry out, it is no longer pliable but hard and brittle, so any attempt to bend it will cause it to break and shatter.

### **Rock Layers Folded, Not Fractured | Answers in Genesis**

Rock folds are found in various shapes and sizes on Earth, and people are often amazed to see how large blocks of hard rocks have been folded like ocean waves. But fascination with folds is also shared by the petroleum industry. In Part I of this two-part article we unfold rock 'folds' to better understand their geometry and genesis.
